

Implications of Current Litigation on the Design of AI Systems for Healthcare Delivery

Abstract

Many calls for explainable AI (XAI) systems in medicine are tied to a desire for AI accountability—accounting for, mitigating, and ultimately preventing harms from AI systems. Because XAI systems provide human-understandable explanations for their output, they are often viewed as a primary path to prevent harms to patients. However, when harm occurs, laws, policies, and regulations also shape AI accountability by impacting how harmed individuals can obtain recourse. Current approaches to XAI explore physicians' medical and relational needs to counter harms to patients, but there is a need to understand how XAI systems should account for the legal considerations of those impacted. We conduct an analysis of 31 legal cases and reported harms to identify patterns around how AI systems impact patient care. Our findings reflect how patients' medical care relies on a complex web of stakeholders—physicians, state health departments, health insurers, care facilities, among others—and many AI systems deployed across their healthcare delivery negatively impact their care. In response, patients have had no option but to seek legal recourse for harms. We shift the frame from physician-centered to patient-centered accountability approaches by describing how lawyers and technologists need to recognize and address where AI harms happen. We present paths for preventing or countering harm (1) by changing liability structures to reflect the role of many stakeholders in shaping how AI systems impact patient care; and (2) by designing XAI systems that can help advocates, such as legal representatives, who provide critical legal expertise and practically support recourse for patients.

Introduction

A growing wave of AI-based applications are developed and deployed for use in healthcare systems. In 2024, over half of the 1500 health AI vendors had been founded in the last 7 years (Economist 2024). There are hopes that AI can improve many aspects of medical care, including workflows, diagnoses, and treatments (Gerke et al. 2020). However, the integration of AI in actual medical settings has had mixed success. Researchers and incidence trackers such as AIAAIC¹ have documented a variety of concerns

¹The AIAAIC is regularly cited and mentioned by academic, non-profit, advocacy, government, and commercial research institutes, associations, and agencies (AIAAIC 2025); <https://www.aiaaic.org/>

including: alert fatigue (Wong et al. 2021); incorrectly prescribing cancer treatments (AIAAIC 2024b); misdiagnosing heart attacks (AIAAIC 2024c; Lomas 2021); wrongly denying opioids (Szalavitz 2024; AIAAIC 2021c); difficulty understanding AI recommendation (Classen et al. 2018); and accentuation of historical and systemic bias for marginalized groups (Benjamin 2019; Abràmoff, Tobey, and Char 2020).

Physicians are—and feel—accountable for the well-being of their patients and their own livelihoods as they use medical AI systems (Mansi, Karusala, and Riedl 2025; Price, Gerke, and Cohen 2019). In response to errors and concerns around harm, many have called for *Explainable AI* (XAI), AI systems that provide human-understandable explanations for their reasoning and output (Lipton 2018; Chari et al. 2020; Guidotti et al. 2018). Explanations support people impacted by AI systems by enabling them to take pragmatic actions in response. That is: they need to be *actionable*. An important class of actionability is *contestation*—a person's ability to push back against an AI system's determinations. For example, a physician may look to an AI explanation to help them make better informed decisions about patient care while calibrating their trust of the AI system and push back against poor AI decisions.

Physicians, AI decisions, and the explanations generated by AI systems do not exist in a vacuum but are embedded in a complex sociotechnical environment (Poquet and de Laat 2021; Šabanović 2010; Jones, Artikis, and Pitt 2013). AI explanations need to support users in acting and responding to the context in which they're situated, including the personal, social, and economic infrastructures that contain knowledge and goals (Poquet and de Laat 2021) that mediate human-AI interactions (Fanni et al. 2022). For example, Ehsan et al. (2021) highlight the importance of presenting socio-organizational factors alongside explanations tied to more technical aspects of an AI system. These aspects of physicians' environments directly impact how they rely on and act in response to AI systems.

One significant sociotechnical dimension for medical physicians and their patients is the evolving landscape of technology and law (Mansi and Riedl 2024; Mansi, Karusala, and Riedl 2025). The last several years have seen large-scale policy changes in response to new technology, unprecedented medical events, and court rulings. This is significant because machine learning systems are not par-

ticularly responsive to rapid changes to the operating environment resulting in differences between the operating environment and the historical data on which the system was trained (Ehsan et al. 2021). Policy changes at the national and local levels impact medical decision making. In the medical domain, for example, the 2020 global pandemic saw the emergency authorization of vaccines and treatments (Commissioner 2024). In 2021, the U.S. Supreme Court issued rulings on women's health, creating an uneven map of where medical procedures could be performed within the country (National Constitution Center 2022). Laws and regulations regarding FDA approval processes for medical devices and software incorporating AI also changed (FDA 2023). Even hospitals' guidelines about treatment can change, such as the kinds of antibiotics or procedures that should be followed. Additionally, there are also regular changes around approved or recommended medications, medical devices, and procedures.

It is critical to inform XAI development with a direct and clear understanding of how contextual dimensions, including laws and regulations, shape physicians' needs from AI explanations. In our study, we conduct an analysis of AI litigation relative to different patient care tasks that physicians engage in to answer the following research questions:

RQ1: What medical tasks performed by physicians are represented in AI-related litigation and reported harms?

RQ2: What are the implications of the current uses of AI systems for how stakeholders—including technologists, legal scholars, researchers, and policy makers—create XAI systems and influence the use of algorithms in medical care?

In our analysis, we map out 31 legal cases and reported harms tied to AI systems that overlap with physicians' tasks when caring for patients. We join well-respected law professors (Oliva 2025; Phillips 2025) in raising awareness that insurers are using AI to deny claims, impeding on physicians' decision-making responsibilities, and thus harming patients. We highlight the conflict in physicians' perceptions of threats from AI systems, and the on-the-ground reality of how their clinical decision making is countered by health insurers. We then discuss the implications for how lawyers and technologists can respond. Based on our findings, we observe that XAI systems for physicians and other healthcare workers are important but not sufficient to reduce patient harms. We advocate for XAI systems that directly support patients *and their legal representatives* in identifying and understanding the impact of the algorithmic determinations across the entire healthcare system.

Background and Related Work

Increasingly, physicians and patients are both leveraging and subject to AI-based applications. Physicians are more widely adopting tools to support their medical documentation efforts or to support administrative tasks (Ryan, Tallaپaka, and Lew 2025). At the same time, they must push back against poorly performing AI alerts about patients integrated into their electronic health record systems (Wong

et al. 2021). At the same time, patients are also negatively encountering AI systems through algorithms that insurance companies use to deny lifesaving care (DAIL 2024c). Given the high-stakes nature of medical decision-making and the growing number of harms reported, the medical community has foregrounded the need for physicians' clinical judgment to support proper human oversight over medical AI (Nystrup and Robinson 2022; Abràmoff, Tobey, and Char 2020; Froomkin, Kerr, and Pineau 2019).

Explainable AI (XAI) has been highlighted as a major path to protect decision makers and decision subjects. *Decision makers* are people that act alongside AI systems to make decisions, serving as buffers between AI recommendations and more vulnerable populations. On the other hand, *decision subjects* are people directly subject to decisions made by an AI system or someone using AI decision-support (Mansi, Karusala, and Riedl 2025). AI explanations are intended to enable physicians as decision makers to use their medical decision making to prevent injury to patients and to advocate for a different course of action than recommended by the AI. That is they aim to make medical AI systems *actionable* and *contestable*. These twin goals extend to patients who are vulnerable to the use of AI systems by both physicians and others such as insurance companies. If a patient is harmed from the use of a medical AI system, they may need explanations to seek legal recourse for harms. While there are incentives for companies to create AI explanations and systems that are actionable for decision makers, such as physicians, they are not always equally incentivized to do so for decision subjects, such as patients, leaving patients vulnerable (Mansi, Karusala, and Riedl 2025).

To make medical AI systems actionable and contestable, XAI systems need to be designed in light of the complex sociotechnical environment of physicians and patients. Physicians must coordinate a wide number of tasks with healthcare workers, administrators and insurers to enable medical care for patients. Patients are similarly embedded in and dependent on a complex network often composed of family, friends, social workers, and healthcare insurers to obtain care. Both healthcare workers and patients must additionally navigate numerous, interlocking hospital and billing digital systems. Laws and regulations further shape the sociotechnical environment, and how AI systems are contestable and actionable, including how AI systems are created, what algorithms can be selected, how safety is measured and determined, how harms are mitigated, and how physicians rely on AI systems in their decision making (Mansi and Riedl 2024).

Physicians' Sense of Responsibility and XAI Systems

Physicians' responsibility for patient outcomes drives their medical, relational, and legal needs around (X)AI systems. Many physicians feel ethically responsible for patient outcomes, whether or not an AI system is involved (Moleman, Regeer, and Schuitmaker-Warnaar 2021; Askitopoulou and Vgontzas 2018). Historically, physicians' relationships with their patients is ethically, professionally, and legally protected. The Hippocratic Oath, an ethical oath taken

by physicians to act in the best interest of their patients, shapes physicians' professional and legal obligations (Askitopoulou and Vgontzas 2018). In practice, medical physicians enact these mandates through nuanced decisions at the intersection of medical knowledge and patients' values and individual needs, such as balancing the effectiveness of a treatment with a patient's quality of life (Moleman, Regeer, and Schuitmaker-Warnaar 2021). Consequently, physicians are and feel responsible for the well-being of their patients and their own livelihoods as they use medical AI systems as well.

Physicians' ethical and professional sense of responsibility is reflected in many HCI findings around XAI medical systems for physicians, including radiologists (Xie et al. 2020; Galsgaard et al. 2022) and specialty clinicians (Yang, Steinfeld, and Zimmerman 2019; Corti et al. 2024), who focus on the importance of integrating XAI recommendations into physicians' workflows to ensure they can protect patients and ensure positive outcomes. For example, when designing an AI-enabled chest x-ray, Xie et al. (2020) found that physicians focused on how the AI's output probability for each conclusion mapped to medical workflows. They emphasized the need to create medical AI explanations based on physicians' perspectives, considering their domain-specific needs and day-to-day practices. Similarly, researchers designing XAI systems for clinicians emphasized the importance of providing explanations that can be dynamically incorporated into conversations between physicians about treatment options for patients (Corti et al. 2024; Gibbs et al. 2021; Galsgaard et al. 2022).

While there's growing attention to designing XAI for stakeholders' legal concerns (Mansi and Riedl 2024; Mansi, Karusala, and Riedl 2025), prior work has mostly focused on designing XAI systems for physicians' medical workflows. Beyond a sense of ethical responsibility, physicians also look to XAI systems to determine if the AI system functions reliably such that they can accept its recommendation without harming the patient and incurring legal repercussions. Currently, physicians are responsible and legally liable for ensuring they are not negligent when making any medical decisions, including when they use AI systems (Sundholm 2024). Physicians' legal concerns around malpractice liability are already pervasive and materially impact medical practices (Nash, Tennant, and Walton 2004; Velthoven and Wijck 2012)—physicians may order more tests and procedures, take more time to explain risks, restrict the scope of their practice, and refer patients to other specialists (Carrier et al. 2010; Dickens 1991; Nash, Tennant, and Walton 2004). Ultimately, the goal of medical AI is to improve patients' quality of care. But this goal can come into tension with physicians' perceived legal risks from AI, and they may opt out of using the system if they feel they are legally at risk. For example, several publications in well-regarded medical journals have warned physicians against potential liability from the use of AI systems (Abràmoff, Tobey, and Char 2020; Price, Gerke, and Cohen 2019). Consequently, XAI systems need to also be made in light of the legal aspects of the medical decision making.

The Role of the Law in AI Accountability

Many of the calls for XAI systems are tied to a desire around AI Accountability—being able to account for, mitigate, and ultimately prevent harms from AI systems. Prominent concerns from AI failures—alert fatigue (Wong et al. 2021); incorrectly prescribing cancer treatments (AIAAIC 2024b); misdiagnosing heart attacks (AIAAIC 2024c; Lomas 2021); wrongly denying opioids (Szalavitz 2024; AIAAIC 2021c); difficulty understanding AI recommendations (Classen et al. 2018); and accentuation of historical and systemic bias for marginalized groups (Benjamin 2019; Abràmoff, Tobey, and Char 2020)—reflect how AI can disrupt tasks that physicians and other healthcare workers often have to coordinate. In response, the medical community has foregrounded the use of clinical judgment as key to enabling proper human oversight over medical AI (Nyrup and Robinson 2022; Abràmoff, Tobey, and Char 2020; Froomkin, Kerr, and Pineau 2019).

The HCI Community has recognized the importance of enabling legal recourse in achieving AI Accountability. A growing body of work has highlighted the importance of enabling legal recourse for correcting harms and enabling collective action in response to algorithms. Lawyers have been recognized for their role as *AI Intermediaries* who navigate legal structures between institutions and stakeholders, interpreting the connections between the harms from using the AI system and the related network of people tied to its use (Mansi and Riedl 2024). Consequently, lawyers play a critical role in the “political process” (i.e. power-related process) of contesting an AI decision in courts, supporting those who seek recourse from AI harms (Karusala et al. 2024). However, lawyers can face a number of challenges in representing vulnerable clients. Prior work has shown how challenges with technology tied to AI systems can undermine lawyers' legal defense, translating to significant consequences for clients and negatively impacting the contestability of AI systems (Warren and Salehi 2022). This complex set of power dynamics between decision makers, decision subjects, and legal representatives has led to calls for *Legally-Informed XAI* (Mansi, Karusala, and Riedl 2025), responding to the need to design AI explanations to account for the legal concerns of those impacted by AI systems, and ultimately ensuring accountability and contestability.

Within the legal community, conversations have been framed around the twin goals of *deterrence*—how to legally incentivize safe deployment to prevent harms before deployment—and *compensation*—how to determine responsibility and just payment once harms occur. Conversations around meeting both these goals range from trying to understand privacy harms and protect medical data (Becker 2025; AIAAIC 2021d) to how the FDA must adapt its review policies for medical devices and software in response to AI systems (Chan 2021; Price 2022; FDA 2023; Sundholm 2024; Gerke et al. 2020). The legal community has also discussed if and how malpractice liability for physicians should change given the wide range of actors involved in the creation, deployment, and maintenance of medical AI systems, which extends far beyond individual physicians' medical decision making (Sundholm 2024). Deterrence and compensation of-

ten go hand and hand. For example, a company may not be deterred from developing and deploying a harmful algorithm if it knows it can significantly profit from the deployment of an algorithm even after financial penalties are levied based on a legal violation. Consequently, it is important to consider how to work alongside lawyers as AI Creators and AI Intermediaries who are identifying and pursuing pathways of deterrence and compensation for those harmed from AI systems.

Methodology

With actionability and contestability in mind, it is critical to inform XAI development with a direct and clear understanding of how contextual dimensions, including laws and regulations, shape needs from XAI systems. Analyzing current litigation and harms can help us identify patterns around how AI systems are impacting the care of patients and how to design XAI systems to support decision makers and decision subjects. Consequently, we adopted a case study approach to analyze documented cases where harms or litigation were reported about an AI technology being developed or deployed in healthcare environments. Our goal was to understand how prevalent legal issues with AI related to physicians' tasks as they tie to patient care. We first gathered real-world cases of algorithms that had harms reported or were litigated, and then conducted an iterative thematic analysis.

To develop our dataset of cases we searched two databases^{2,3} known to track health care litigation in the United States for instances where lawsuits were raised because of AI systems involved in healthcare delivery. Because some significant harms or negative impacts might happen but not be litigated, we also searched for harms reported through the AIAAIC Database, a public interest initiative that collects and classifies issues driven by and relating to AI, algorithms, and automation. The AIAAIC is regularly cited and mentioned by academic, non-profit, advocacy, government, and commercial research institutes, associations, and agencies (AIAAIC 2025).

From the cases that met the criteria, we selected a subset of 31 case studies for our thematic analysis. We chose this subset based on several criteria, including (a) If patient care was or could be impacted, (b) If the harm overlapped with a task physicians normally take in patient care; and (c) if the harm or legal case occurred in the United States. We only considered cases or harms that occurred in the United States because international laws and litigation process can differ greatly. We found entries tied to the deployment of AI systems with social workers and nurses (AIAAIC 2024c, 2022), but we excluded these cases either because they did not take place in the U.S or they did not impact medical decision making in a clinical setting. While their roles in patient care are important and their XAI needs are also important to consider, all cases (and consequently our analysis) centered on

²Database of AI Litigation (DAIL), George Washington University of Law, <https://blogs.gwu.edu/law-eti/ai-litigation-database/>

³Health Litigation Tracker, Georgetown University Law Center, <https://litigationtracker.law.georgetown.edu/>

AI systems that impacted patient care by U.S. physicians.

Our final case set included 12 entries about legal cases and 19 entries about harms reported from 2021 to 2024.⁴ These legal cases and harms are not intended to be a comprehensive list of all cases and harms from medical AI systems, but rather serve as a starting point to illustrate emerging dynamics of many legal cases and harms.

Working with a physician on our team, we iteratively created a list of 10 definitions and examples of tasks physicians undertake when caring for patients. Tasks ranged from more patient-facing, such as clinical decision-making and disease monitoring, to less, such as professional education and practice management. For each task, we created a set of example physician activities that could be used to further guide our analysis.

We gathered and reviewed public sources about each case, including news articles, legal documents, and other primary sources. In our thematic analysis we took special note of which kind of physician task the AI system overlapped with. If it was a legal cases, we took note of the general legal issue over which the case was taking place (e.g. malpractice, privacy), who were the primary defendants and prosecutors, and, if other sources were available, other complaints or concerns outside of the issue represented in the litigation. If it was a harm, we took note of the general issue over which the system was criticized, and the primary concern or harm from the system's application. We then iteratively organized each legal case or harm according to the main physician task that it overlapped with. If a case or harm overlapped with more than one physician task, we coded it with all related tasks. Three example cases are in Figure 1, and a complete list is given in the Appendix.

Findings

Most legal cases and harms centered on AI systems that infringe on physicians' clinical decision making. Of the 12 legal cases we identified, 11 of them involved an AI system tied to Clinical Decision Making. The other legal cases we in our review was tied to Preventative Care. Clinical Decision Making was also the physician task associated with the most harms (12); followed by Disease Diagnosis (4); Preventative Care (2); Practice Management, Care Coordination, Medical Documentation, and Disease Monitoring/Management (1). No harms or legal cases in our review were tied to AI systems involved in Medical Research, Quality Improvement, or Professional Education. Figure 2 shows the distribution.

⁴The tallies of legal cases and entries about harms are absolute numbers of the total cases we found across all databases, including entries from different databases mentioning the same legal case. There were 5 entries that covered overlapping legal cases across databases, and 3 harms entries that overlapped. Because AIAAIC and the litigation trackers are living databases—actively updated and maintained by the community—they could contain different information. Further, they could cover different aspects of harm presented to patients. Consequently, we opted to keep and cite all duplicates independently, rather than selecting one.

Case/Harm	Task Reason
Ark. Dep't of Human Servs. V. Ledgerwood DAIL: Low income plaintiffs with physical disabilities sued the Department of Health Services, which replaced their nurse assessment questionnaire to an algorithm that drastically reduced attendant care, overriding physicians' decisions for necessary care	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
US Veterans Affairs suicide prevention algorithm favors white men AIAAIC: A US Department of Veterans Affairs (VA) AI program to predict suicide risk and flag veterans to provide extra help; found to prioritize white men and overlook survivors of sexual violence	Preventative Care Engages in preventative care because the AI helps patients navigate health challenges through screening and intervention, flagging veterans for extra help based on suicide risk
Study: Whisper AI transcription invents medical treatments AIAAIC: Open AI's transcription tool Whisper is prone to generating "hallucinations" when transcribing audio, including racial commentary, violent rhetoric, and imagined medical treatments; prompted concerns about its use in hospitals	Medical Documentation Engages in medical documentation because the AI transcribes audio for documentation

Figure 1: This figure shows three cases used in our case study analysis of harms or litigation involving AI technologies in medical settings. In our analysis cases are organized according to physician task (colored box) along with a summary reason for the classification.

Patterns Across Clinical Decision Making

The minority of the harms related to AI systems and Clinical Decision Making directly involved physicians. Only 2 of the 11 harms associated with Clinical Decision Making were tied to algorithms intended to directly interact or interface with physicians. IBM's Oncology Expert Advisor (OEA) was supposed to provide personalized cancer treatment recommendations to physicians at the MD Anderson Cancer Center (AIAAIC 2017, 2024b). Similarly, harms to patients were reported around a Google Cloud (AIAAIC 2021d) collaboration in which the company was supposed to analyze data to create algorithms for patient monitoring and medical decision making.

Most of the harms and legal cases tied to Clinical Decision Making originated from the use of AI systems by stakeholders other than physicians. Nine of the 11 harms and all 11 of the legal cases involved the use of AI systems for determinations tied to clinical decision making by non-physician entities. For example, several prominent lawsuits involved U.S. states, including Arkansas (DAIL 2021a), West Virginia (DAIL 2019), Idaho (DAIL 2021b), Oregon (DAIL 2023a), and Tennessee (AIAAIC 2024d), that used AI systems to cut resources and change the allocation of health benefits, often using trade secret algorithms to make determinations. Similarly, most of the other harms and legal cases reported involved health insurance companies that used AI systems to deny claims, hindering patients from medically necessary treatments (AIAAIC 2023d,f,e, 2024a, 2023a, 2024e, 2019; DAIL 2023c; O'Neil Institute 2023; AIAAIC 2023c; O'Neil Institute 2025a; AIAAIC 2024g; DAIL 2024b; O'Neil Institute 2025b; DAIL 2024c).

AI systems used by other stakeholders do not involve the patient's physician, but they make AI determinations that

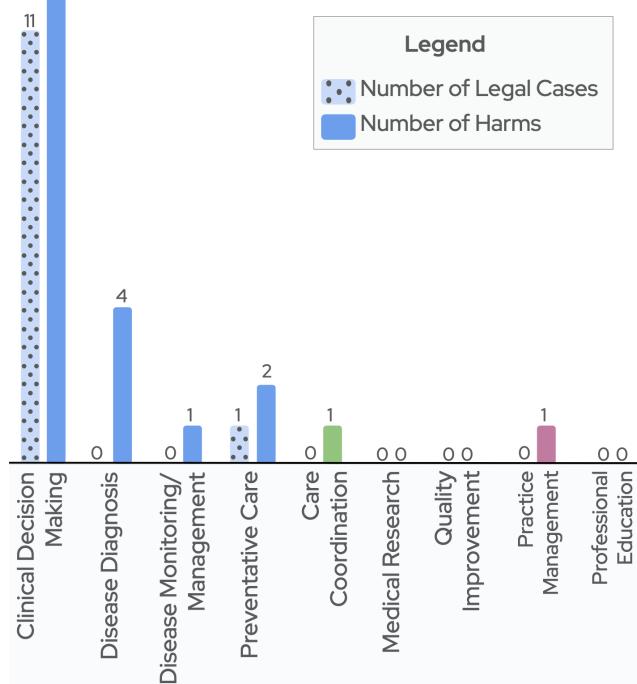

Figure 2: The distribution of legal cases and harms across physicians' tasks. Most legal cases and harms centered on AI systems that infringe on physicians' clinical decision making.

contradict physicians' clinical decision making and create negative patient outcomes. For example, several prominent legal cases involve a health insurance company that denied medically necessary care to elderly patients based on an AI prediction of patient recovery times (AIAAIC 2024g; O'Neil Institute 2025a; DAIL 2024c). Even when physicians and medical documentation clearly indicated a patient needed much longer to recover, the decisions made by these AI systems overruled the physician determination and patients' claims were denied. In this way, these systems were effectively providing surrogate clinical decisions that materially impacted patients' medical care.

A Snapshot of People Impacted

Across all harms and litigation, most AI systems were made to make determinations primarily for vulnerable populations, such as the elderly (Ross and Herman 2024; AIAAIC 2024g, 2023d,e,f; DAIL 2024b; O'Neil Institute 2025b), those facing physical disabilities (DAIL 2021a,b, 2019, 2023a; AIAAIC 2024d), and those with mental health challenges (AIAAIC 2024e). No harms or legal cases involved malpractice liability or claims in which physicians were suing or being sued for decisions made alongside AI systems.

Lawsuits were undertaken by either private individuals who had been impacted by the system or by advocacy groups, such as the ACLU. Further, cases involving public systems, such as those used by states, were often

stopped more quickly given determinations impacted vulnerable populations, violating their rights. State judges ordered injunctions, which require the state to immediately stop using the system, and ordered states to restore use of their previous algorithms for resource allocations. On the other hand, algorithms deployed by private companies were deployed for longer and often only stopped when private individuals sued companies and initiated class action lawsuits.

Patterns Across Physicians' Other Tasks

Most AI harms and litigation outside of clinical decision making involved systems deployed for use by physicians or healthcare workers. Our review included a total of 11 harms and legal cases in Monitoring/Management, Disease Diagnosis, Preventative Care, Care Coordination, Medical Documentation, and Practice Management. Notably, just under half of harms (5 of 11) involved systems intended for use by physicians, but most of these systems were retracted in response to complaints around poor performance.

Discussion of Findings

Because laws and regulations significantly shape how technology is developed, lawyers and technologists play a joint role in enabling AI accountability given the challenges that patients are facing. Physicians desire XAI systems because they see themselves as primarily responsible for negative patient outcomes from AI systems using in medical decision making (Mansi, Karusala, and Riedl 2025; Price, Gerke, and Cohen 2019). However, the harms and legal cases we reviewed point to the ways in which patients' *medical care relies on a complex web of stakeholders* who all play a role in healthcare delivery and contribute to patient outcomes. As seen from our analysis of AI harms and legal cases, there's a lack of malpractice cases. Instead, AI systems are being deployed across patients' healthcare delivery by actors—state health departments, health insurers, and care facilities—in ways that disrupt and negatively impact their outcomes. In the following section, we discuss the implications for both lawyers and technologists about how to think about, develop, and deploy XAI systems that truly protect patients.

A Noticeable Lack of Malpractice Cases

While physicians have expressed concerns around malpractice liability and harms to patients from the spread of AI systems in healthcare, *none of the legal cases in our review involved malpractice claims.* There could be several reasons for this.

First, while physicians are expanding their professional use of AI systems, the majority of physicians are not using AI systems in their workflows. In a survey of over 1200 primary care physicians by Rock Health, a prominent venture fund focused on healthcare technology, reported that 32% of respondents use AI for Medical Documentation and 23% use AI for Clinical Decision Support (Ryan, Tallapaka, and Lew 2025). While both of these uses are important for malpractice cases, most physicians are not using AI systems for these purposes. Consequently, there may be a lack of legal

cases involving malpractice simply because these tools are not in widespread use.

Second, even if an AI system is used for Clinical Decision Making, it may be hard for patients to identify the involvement and impact of the system on their physicians' decision making. Malpractice suits are raised when a patient feels the physician has been negligent in their care, resulting in injury. For a patient to raise a lawsuit against a physician because of their AI use, the patient would need to know (a) an AI system was involved; and (b) their physician acted negligently with it—both of which may be hard for patients to determine.

Third, physicians are legally protected by high professional and industry standards for medical devices deployed for their use. While most decisions about which AI tools to use are made at the organizational level by an executive, physicians' buy-in around these tools is critical to their success. As can be seen from the harms in our review, poorly performing applications intended for use by physicians were retracted before lawsuits were brought to bear. Given the high stakes, inherent risks, and desire for consistency from employers, physicians have a powerful voice when a tool significantly disrupts their abilities to care for patients. Consequently, tech companies and hospitals may be more careful in the tools they deploy to physicians and more responsive to physician complaints about poor or harmful performance.

AI Accountability is Physician-Centered

Over-focusing on harms from AI systems used by physicians obscures where harms are actually befalling patients. Physicians are traditionally trained to undertake responsibility for themselves and those around them, and thus may express the most concern around AI systems that make poor medical determinations—reflecting a physician-centered notion of accountability. Similarly, conversations around XAI systems and AI Accountability are also physician-centered as they largely focus on ensuring medical decision makers, especially physicians, are provided XAI systems that help them protect patients from AI determinations. Our findings indicate that physician-centered notions of accountability provide a limited perspective on how harms from medical decisions with AI systems may occur.

Patients are experiencing and combating harms in many areas beyond physicians' control and in ways that current XAI systems do not address. As depicted in Figure 3, there are many actors who can use AI systems that impact patient care⁵. While some, such as physicians and nurses, have deep incentives to work in the interests of patients, others, such as healthcare insurers do not always have incentives that align with patients' interests. As shown in Figure 4, healthcare insurers (AIAAIC 2024g; O'Neil Institute 2025a; AIAAIC 2023c,f; DAIL 2024b; O'Neil Institute 2025b; AIAAIC 2023d, 2024a; DAIL 2023c, 2024c;

⁵Our figures are not intended as an exhaustive display of actors who are involved in medical decision making. We chose to represent these two groups visually since their other roles in patient care are established and their needs are also important to consider when building (X)AI systems for patient care as can be seen from reported harms (AIAAIC 2024c, 2022).

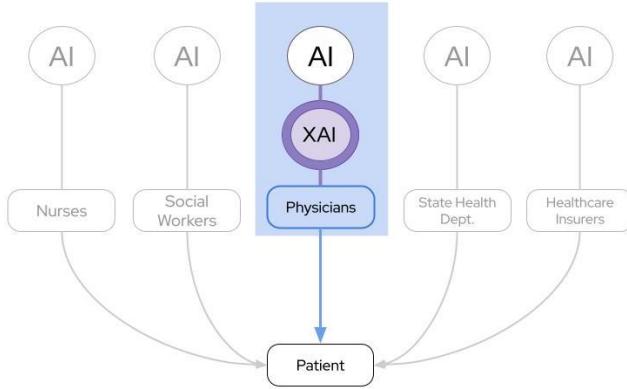

Figure 3: Many in the medical community and those engaged in regulating medical AI are concerned about how to develop and deploy XAI systems with physicians to prevent patient harm. Our findings demonstrate that many other actors are using AI systems and impacting patients.

AIAAIC 2024e, 2019, 2023b), national and state health departments (AIAAIC 2024f; DAIL 2021a,b, 2019, 2023a), and private companies (AIAAIC 2021b,e,c, 2024c, 2021a; DAIL 2023b, 2020, 2024a; AIAAIC 2024d) are empowering themselves to determine patient diagnoses, care, and monitoring—*independent* of patients or their physicians.

While it's valuable to design for physicians' sense of medical and legal responsibility in XAI systems for clinical workflows, it is important to recognize the limited nature of protecting patients based on a physician-centered notion of accountability. Prior work around designing for stakeholders' legal needs has also focused on topics tied to physicians' legal concerns, such as those around malpractice liability (Abràmoff, Tobey, and Char 2020; Price, Gerke, and Cohen 2019). Further, XAI systems for physicians have mainly targeted physicians' medical workflows and relational needs (Xie et al. 2020; Galsgaard et al. 2022; Yang, Steinfeld, and Zimmerman 2019; Corti et al. 2024). But patients must potentially interact with AI systems throughout their entire healthcare delivery experience, from chatbots used to help with scheduling (Clark and Bailey 2024) to clinical decision making systems (AIAAIC 2017, 2019) to AI-based claims approval (AIAAIC 2023c) to AI determinations on disability services that can force patients to forgo treatments (DAIL 2021a, 2019; AIAAIC 2024d,a; DAIL 2023c; O'Neil Institute 2023). However, XAI approaches built for physician-centered notions accountability do not address or reflect many of the current harms patients are or could experience from other stakeholders.

Implications for the Legal and XAI Communities

Examining harms from a patient-centered perspective on AI accountability highlights how patients are experiencing harms from AI systems deployed across healthcare delivery. Reframing AI accountability in response to a patient-centered perspective of harms can bring to light opportuni-

ties for building XAI systems and legal pathways that are actionable and contestable *by patients*. In this section, we draw on patterns in our findings to describe opportunities for the XAI and legal communities to respond to harms and enable patients to push back against harmful AI-based medical decisions.

Legal Recourse Within Healthcare's Complex Web of Responsibility

Our analysis shows that clinicians aren't responsible for care or harm in all circumstances when AI systems are used for medical decisions impacting patients. They are responsible only in proportion to the contribution of other actors, such as software developers, health system administrators (who increasingly decide which AI solutions to purchase), health insurance companies, and others. *Reassessing the legal structures that contribute to deterrence and compensation from a patient-centered perspective can better align accountability with the landscape of harms observed through our analysis.*

The complex web of people and their responsibilities is not fully reflected in the law when it comes to harms and accountability from the use of AI systems in medical decisions. Recent court decisions and laws focus on physicians' responsibilities in protecting patients, indicating that physicians will still be held fully liable for the use of AI tools in the care of patients. Our analysis highlights how unregulated algorithms leads to improper claim denials and delays in patient care with life altering consequences for patients; also noted by other legal scholars (Oliva 2025). Ignoring critical aspects of recourse, such as the appeals process, and reforming only certain government programs can leave patients vulnerable to similar applications of AI systems (Oliva 2025; DAIL 2021a).

Even though companies and administrators play a significant role in how patients are negatively impacted by AI systems, they displace responsibility to protect patients onto physicians by leaving them to veto poor AI determinations. AI systems are highly dependent on the way data is curated, processed, and packaged by a company, drastically shaping its operation long before physicians are asked to use it (Singhal et al. 2023). Hospital administrators, who are often not the ones using the system or caring for patients, then choose which technologies to purchase and require physicians to use (Ryan, Tallapaka, and Lew 2025). Consequently, physicians—who are only one group of many actors shaping AI systems in patient care—have good reason to be concerned about current liability structures as they relate to the deployment of AI systems and the safety of their patients (Price, Gerke, and Cohen 2019). As shown in Figure 4, many other actors are overriding physicians' clinical decision making to the detriment of patients.

Changing legal responsibility structures to reflect the aggregate responsibility of all stakeholders using AI systems can begin to deter harmful AI deployment and compensate patients and physicians for harms. There are several ongoing conversations in the legal community that speak to the asymmetries in responsibility over medical AI systems. For example, legal scholars (Sundholm 2024; Price 2022; Chan 2021) are discussing distributed models of risk where physi-

cians, AI creators, hospital administrators, and other stakeholders share legal responsibility when patients are harmed from the use of AI systems. This may better deter companies or administrators from deploying AI systems and leaving physicians to protect patients. It may more equally reflect the shared responsibility of stakeholders in how patients are compensated when they are harmed.

Finally, re-evaluating the acceptable uses of AI systems by insurers and private companies can help guide the development of guidelines that better protect patients and their physicians. For decades, scholars have warned against the commodification of medicine as a trend that fractures the relationships between physicians and their patients (Pellegrino 1999). AI systems exacerbate health insurers' and private companies' existing financial incentives to place profit above the health of the patients. Without changing either financial incentives or legally permitted applications, patients are at risk and will continue to bear an unfair burden of harms and challenges when contesting AI determinations across healthcare delivery. When discussing the healthcare applications of generative AI, the National Academies of Medicine stated that “policy makers and regulators are essential collaborators in almost all key phases of the development and deployment... responsible for *creating the necessary incentives* for action and *enforcing the best practices and standards*” (emphasis added) (Maddox et al. 2025) . Evaluating existing laws and regulatory structures in light of patient harms and vulnerabilities can guide discussions around incentives and guidelines, such as whether to grant the FDA more authority and sufficient resources to review applications of AI systems (Oliva 2025; Phillips 2025), and banning uses of AI systems in medical decisions that impact patient care.

Re-framing XAI for Patient-Centered Accountability

Adopting *patient-centered* notions of accountability holds implications for how the HCI community should design XAI systems that support patients. Much of the research on contestation has focused on technical measures, such as counterfactual explanations that indicate how those subject to AI decisions, such as patients, could have achieved better outcomes from the system. Our analysis helps expose why a technical approach will likely not achieve AI Accountability for patients or others who are unjustly impacted.

The importance of a patient-centered approach stems from the observation that *XAI systems for healthcare workers—including physicians, social workers, and nurses—are important, but not sufficient, to protect and support patients*. Because private companies’ incentives differ from those of physicians and patients, companies cannot be relied on to self-regulate their applications or provide explanations that will serve patients. Several lawsuits we reviewed demonstrate how companies, under the pretense of preventing fraud, use AI systems to make financially profitable health determinations that negatively impact patients without the review of a physician (AIAAIC 2021c, 2024e). Many others involved systematically denying covering while overriding physician recommendations

(AIAAIC 2024g; O’Neil Institute 2025b; AIAAIC 2023f,d; DAIL 2024b; O’Neil Institute 2025b; AIAAIC 2024a; DAIL 2023c, 2024c). Further, as seen in our analysis from the previous section, and in prior work (cf. (Ross and Herman 2024; Metcalf et al. 2023)), users, developers, and deployers of AI systems can use the black-box nature of the system to evade liability.

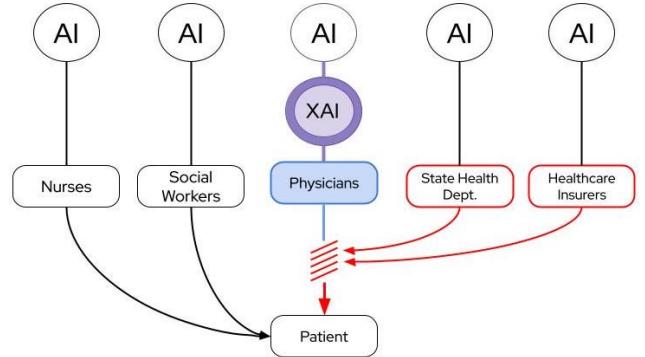

Figure 4: Some actors who use AI, such as physicians, nurses, and social workers have incentives aligned with patients. Others who use AI, such as state health departments and healthcare insurers, don’t always have incentives aligned with patients. However, these actors may make AI-supported decisions that significantly disrupt or functionally override the decisions of physician (or others). Consequently, XAI systems for physicians are important but not sufficient to protect and support patients.

XAI for Advocates *Designing XAI systems that patients’ legal representatives can leverage is critical for vulnerable patients to fight powerful stakeholders, such as healthcare insurers, in the courts.* Our examination of our data verifies what others (Mansi and Riedl 2024) have postulated: the critical role of legal representatives and other advocates in AI Accountability. As demonstrated in our analysis, patients are currently left to advocate for themselves in the courts. Physicians, nurses, and social workers can only get so far advocating for patients through infrastructures internal to hospital environments. Because companies can deploy systems that disrupt the relationship between patients and their physicians, patients can be left with no other option but to seek legal recourse. Even in the context of AI in public services, where there is ostensibly more accountability, regulatory environments, democratic structures, and input of legal experts can also shape contestation of AI systems; those with more legal know-how are at an advantage in contesting systems (Alfrink et al. 2023).

Furthermore, prior work investigating how marginalized groups contest decisions has confirmed significant inequities in access to navigational support, including legal expertise, that could help engage with bureaucracies, construct effective appeals, and gain insight into AI systems across multiple decisions (Karusala et al. 2024). A number of lawsuits we reviewed were class action lawsuits (DAIL 2021b; AIAAIC 2023c; DAIL 2024b; AIAAIC 2024d), which re-

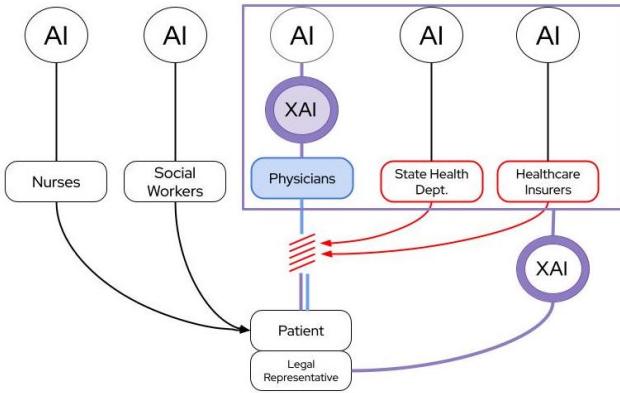

Figure 5: XAI systems for legal representatives should help them identify and understand both the algorithmic and human factors that impact patients. The large purple box in this diagram represents a potential XAI system that helps legal representatives understand the AI systems used by physicians, state health departments, and healthcare insurers to make decisions⁶.

flect repeated errors and harms across individuals. Those that were not initiated by individuals were undertaken by public advocacy groups (DAIL 2021b; AIAAIC 2024d), further pointing to collective public harm and significant barriers to seeking recourse by individual patients.

XAI systems are needed that can help patients' legal representatives make sense of both the human and social elements of AI-supported decision making that they can already glean alongside more technical dimensions of how AI systems operate. Legal representatives play a critical role advocating for patients by examining evidence from a case, and integrating it with legal information to construct a narrative that can persuade a judge or jury to act in favor of their client's perspective (Mansi and Riedl 2024). Legal representatives are trained to seek information about human reasoning—such as identifying physicians' negligence in medical decision-making with an AI system. However, they are less equipped to identify and understand the impacts of more opaque, algorithmic aspects of AI systems used by the many stakeholders in healthcare delivery. This includes physicians but also extends to impacts of AI systems used by healthcare insurers, governmental entities that determine benefits, hospital administrators, and others. Further, AI systems integrated into workflows across healthcare delivery can have a compounding effect. For example, it may be important to help a legal representative understand the joint impact of both a physician's use of AI and a healthcare insurer's use of AI on a patient's health outcome. Consequently, creating XAI systems that help legal representatives identify and understand the impact of the algorithmic determinations that patients undergo across healthcare delivery can support patient-centered AI accountability.

⁶Each of the stakeholders in the box could also have individual XAI systems that could be explained, such as the one displayed with the physicians. Further, the XAI system for legal representa-

Actionability in Healthcare Ecosystems There is also need to consider what constitutes an actionable XAI system for legal representatives and patients, including who needs access to XAI systems and what kinds of information should be provided. Currently, many approaches to AI Accountability call for AI deployers to create XAI algorithms, so others can audit, understand, and contest how AI decisions are made. While underlying algorithms often cannot be revealed, these AI systems work as "wrappers", providing justifications for decisions to support greater transparency. This means that explanations are likely geared towards *decision makers* (e.g. physicians), who are in a position and role to make informed decisions based on the recommendations of the AI system, rather than *decision subjects* (e.g. patients) to whom the AI-supported decisions apply. Further, the explanations that are given directly to decision subjects may not convey actionable information that would be to the benefit of the decision subject and to the disadvantage of the decision maker. Thus, there is risk that explanations may be presented in the form of *dark patterns*—explanations intentionally designed to discourage actionability (Chromik et al. 2019)—or *explainability pitfalls*—explanations that unintentionally have that effect (Ehsan and Riedl 2021).

While it is still valuable for governmental entities to regulate AI systems, the slow pace of regulation also points to the need for XAI systems through which patients themselves and their advocates can seek recourse. In the United States, the wait-and-see approach to legal regulations around medical AI means that the courts will likely be slower to act and deter future harms for patients and physicians. The Food and Drug Administration (FDA), which has historically been tasked with validating and ensuring the safety of medical devices and software, is highly dependent on governmental authorization. The FDA could be slowed by bureaucratic complexity to uncover and adapt to new harms as medical AI applications diversify or have trouble validating the safety of AI systems given the diversity of patient populations who may be impacted (Price 2022). As a result, patients and their legal representatives will still need information from AI systems that they can use to push back against inappropriate or harmful applications.

Addressing the challenge of ensuring that legal representatives can integrate information from AI systems or audits to defend their clients is an important aspect of developing actionable XAI systems. Lawyers can encounter barriers to building cases against companies that deploy AI systems despite access to performance evaluations of said systems. Beyond access, they also face difficulties understanding how these technologies are developed and used (Jin and Salehi 2024). The HCI community has recognized that XAI solutions are not limited to algorithmic explanations or showing model internals, and can also incorporate different aspects of an AI system's context when explaining AI-mediated decision-making (Sun et al. 2022; Ehsan and Riedl 2020, 2021; Ehsan et al. 2024; Kaur et al. 2022; Chen et al. 2025). AI systems in healthcare are embedded in a complex so-

lutions could also be expanded to account for other stakeholders, such as nurses and social workers who use AI systems.

crotechnical environment with people who may have conflicting uses, roles, and relationships to patients. XAI systems can empower patients and their legal representatives to seek recourse by helping them understand both the algorithmic and human factors that impact an AI-mediated decision. Figure 5 shows this conceptualization.

To help patients and their legal representatives determine and pursue contestation as an appropriate, actionable response, XAI systems must incorporate information that supports lawyers as they act as Intermediaries and AI Creators in XAI systems. Prior work has identified two kinds of legal information that could be incorporated into XAI systems to support patient-centered accountability (Mansi, Karusala, and Riedl 2025). *Legally informative* information explicitly describes laws, regulations, and legal rights that are relevant to those impacted by the AI system. On the other hand, *legally actionable* information can be used for legal action once harm has occurred, but is not legally related in and of itself. For example, it may be helpful to include information about whether others have chosen to accept or contest their decisions in the past, why, and how the decision was contested. Identifying both of these kinds of information and making them accessible to the legal representatives of those who are harmed can help them more easily advocate for those who are harmed.

Conclusions

When harm occurs from XAI systems in medicine, laws and regulations shape AI accountability, including how individuals are able to seek recourse. Many in the medical community and those engaged in regulating medical AI have called for XAI systems for physicians to prevent and mitigate harms. However, there is need to understand how to design XAI in light of the legal considerations of those impacted as well. We analyzed 31 legal cases and documented harms pertaining to AI use in healthcare. We identify a pattern where non-physician actors such as health insurance companies and state health departments significantly disrupt or functionally override the decisions of physicians, leaving patients no choice but to seek legal recourse. We highlight the value of reshaping legal structures to reflect the complex web of stakeholders who impact patient care, for example, through shared liability.

We also identify how XAI systems for physicians—while important—are not sufficient to protect patients from harms or help them seek recourse when harms occur. By centering the patient instead of the physician, we identify a path to expand XAI to patients and their advocates. We call for XAI systems that support patients as they seek recourse. Addressing the unique information requirements of patients' legal advocates and representatives can significantly improve patients' abilities to seek and obtain recourse for harms, re-empowering patients to push back against harmful medical decisions.

Appendix: Physicians' Tasks

Working with a physician on our team, we iteratively created a list of 10 definitions and examples of tasks physicians undertake when caring for patients. Tasks ranged from more patient-facing, such as clinical decision-making and disease monitoring, to less, such as professional education and practice management. For each task, we created a set of example physician activities that could be used to further guide our analysis.

Task/Definition	Examples
Clinical Decision Making The process of evaluating available information about a patient and engaging with patients in shared decision-making about treatments, medications, and further testing	<ul style="list-style-type: none">• Shared decision-making discussions• Goal setting with patients• Counseling about risks and benefits of different treatments
Disease Diagnosis Identifying the disease or condition causing a patient's symptoms or health issues	<ul style="list-style-type: none">• Explaining diagnosis with patients• Physical exams, blood work, imaging
Disease Monitoring/Management Tracking how a condition is progressing and adjusting treatments as needed	<ul style="list-style-type: none">• Checking key health indicators• Re-evaluating with patients how well treatments are working and making adjustments as necessary
Preventative Care Helping patients avoid or navigate future health problems through screenings, vaccinations, lifestyle guidance, and early intervention when risk factors appear	<ul style="list-style-type: none">• Teaching patients about lifestyle changes• Helping patients understand impacts of testing results on their lifestyles• Conducting tests such as mammograms or colonoscopies
Care Coordination Coordinating with other specialties and health professionals involved in the multi-disciplinary care of patients	<ul style="list-style-type: none">• Communicating with and coordinating care with physicians in other medical specialties• Coordinating care with social workers or financial aid services
Medical Documentation Completing necessary paperwork and documentation for proper continuity of care and communication	<ul style="list-style-type: none">• Writing medical records• Writing prescriptions for medications
Medical Research Advancing knowledge about medical conditions, diseases, or treatments	<ul style="list-style-type: none">• Conducting and sharing clinical research• Publishing and presenting work on medical outcomes
Quality Improvement Conducting data-guided activities to bring about immediate improvements in health care delivery and improve patient experiences	<ul style="list-style-type: none">• Implementing a new process for patient safety or flow• Monitor how care delivery changes impact workflow, cost effectiveness, or staff expertise
Practice Management Performing activities (often in a smaller practice) to support the administrative and operational aspects of a practice	<ul style="list-style-type: none">• Running staff meetings in a small practice• Billing and coding health insurance forms for patients• Conducting patient follow up tracking and communication• Ensuring regulatory compliance (e.g. HIPPA)
Professional Education Teaching and training other doctors or healthcare professionals	<ul style="list-style-type: none">• Teaching medical students or residents

Figure 6: The physicians' tasks, definitions, and examples that we created and referenced as we analyzed legal cases and harms. Tasks at the top of the list are more patient facing, and are increasingly less patient facing further down.

Legal Cases and Harms

Below we list all 31 of the legal cases and harms that we included in our study, along with our reasoning for categorizing it as a specific physician task.

Case/Harm	Task
Database: Description	Reason
IBM's Oncology Expert Advisor fails to deliver on promises AIAAIC: IBM Watson for Oncology used synthetic data to train its AI system designed to assist doctors in cancer treatment decisions. Internal documents revealed doctors reported unstable performance and concerns about reliability.	Clinical Decision Making Engages in clinical decision making because the AI provided personalized treatment recommendations
IBM Watson recommends "unsafe and incorrect" cancer treatments AIAAIC: An algorithm deployed one of largest electronic health record companies in the US to predict sepsis missed approximately 63% of cases, leading to alert fatigue by medical staff, potentially delaying treatment and contributing to poorer patient outcomes.	Clinical Decision Making Engages in clinical decision making because the AI provided personalized treatment recommendations
Study: Epic sepsis model misses two-thirds of cases AIAAIC: An algorithm deployed one of largest electronic health record companies in the US to predict sepsis missed approximately 63% of cases, leading to alert fatigue by medical staff, potentially delaying treatment and contributing to poorer patient outcomes.	Disease Diagnosis Engages in disease diagnosis because the AI identified a condition, sepsis
Google Derm Assist dermatology app accused of racial bias AIAAIC: An AI-based app designed by Google to automatically analyze skin conditions, ask questions, and suggest causes; Some doctors expressed concerns about the accuracy of the system and the potential overdiagnosis of skin cancers	Disease Diagnosis Engages in disease diagnosis because the AI identified a condition, different skin cancers
"Clinical grade" AI stress detector fails to work AIAAIC: Cigna's StressWaves Test is a free online tool that uses voice recognition to evaluate and reveal stress. The tool gives inconsistent results when tested on the same person twice, calling into question its efficacy and marketing claims	Disease Diagnosis Engages in disease diagnosis because the AI identified a condition, stress level
Stanford hospital COVID-19 vaccine allocation algorithm triggers backlash AIAAIC: A rule-based, algorithmic COVID-19 vaccine distribution system developed and run by Stanford Medicine came under fire for prioritizing certain staff members.	Practice Management Engages in practice management because the AI made an administrative decision in running a practice about distribution of vaccines among staff members
US Veterans Affairs suicide prevention algorithm favors white men AIAAIC: A US Department of Veterans Affairs (VA) AI program to predict suicide risk and flag veterans to provide extra help, found to prioritize white men and overlook survivors of sexual violence	Preventative Care Engages in preventative care because the AI helps patients navigate health challenges through screening and intervention, flagging veterans for extra help based on suicide risk
NarxCare drug addiction risk assessment system wrongly denies patients opioids AIAAIC: AI-based system used to determine the risk of drug addiction and used to deny users opioids, accused of reinforcing existing racial and gender bias, and worsening patient health because of denials	Preventative Care Engages in preventative care because the AI helps patients navigate health challenges through screening, flagging patients for risk of drug addiction
EPA Emergency Severity Index accused of racial, economic bias AIAAIC: AI-based system used to triage patients and identify patients for rapid assessment; found to underestimate black and hispanic peoples' problems, perpetuating inequitable treatment	Care Coordination Engages in care coordination because the AI helps coordinate health professionals in the care of patients, by triaging patients, shaping how patients are seen by providers
Kisting-Leung et al. v. Cigna Corporation et al. O'Neil Institute Tracker: Class action lawsuit in California alleging that Cigna used an algorithm to wrongfully deny claims to patients seeking care recommended by medical providers	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care, forcing patients to forgo important procedures or pay substantial out-of-pocket costs
Van Pelt v. Cigna Group DAIL: Class Action lawsuit in Connecticut alleging that Cigna's automated systems allows its medical directors to automatically deny medically necessary claims without even opening patient medical records	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that help the health insurance companies' clinicians to overrule the clinical decision making of patients' physicians
Cigna PxD accused of accelerating health insurance claim denials AIAAIC: Cigna's PxD system enables doctors employed by Cigna to reject patients' claims (includes those approved and deemed medically necessary by the patient's doctor) using a bulk electronic signature without opening or reviewing their files, and to save money by turning down claims it had once paid	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that help the health insurance companies' clinicians to overrule the clinical decision making of patients' physicians
UnitedHealth Group algorithm accused of systematically limiting mental health coverage AIAAIC: Repurposed suite of algorithms used by UnitedHealth to identify patients receiving what it considers excessive mental health therapy, led to denials of coverage for many individuals, despite being banned in three US states (CA, MA, NY)	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care, preventing access to necessary mental health care
Study: UnitedHealth follow-up care algorithm is racially biased AIAAIC: Designed to predict patient health risks and allocate follow-up care, UnitedHealth's AI system classified white patients as being sicker than Black patients with similar health conditions.	Preventative Care Engages in preventative care because the AI helps patients navigate health challenges, flagging patients for follow up care

Figure 7: The legal cases and harms we tracked in our case study. We include the name of the case, the database in which we found it, the physician task it corresponds to, and the reason for categorizing it under certain tasks.

Case/Harm	Task
Database: Description	Reason
Study: Whisper AI transcription invents medical treatments AIAAIC: Open AI's transcription tool Whisper is prone to generating "hallucinations" when transcribing audio, including racial commentary, violent rhetoric, and imagined medical treatments; prompted concerns about its use in hospitals	Medical Documentation Engages in medical documentation because the AI transcribes audio for documentation
Privacy advocates raise concerns about Google patient data deal with HCA Healthcare AIAAIC: Collaboration between a major US hospital chain and Google to enhance operational efficiency develop algorithms for patient monitoring and medical decision making	Clinical Decision Making Disease Monitoring By description, engages in clinical decision making and disease monitoring
Dinerstein v. Google, LLC DAIL: Collaboration between Google and University of Chicago to share data and create a predictive health system to prevent patients from having to return to the hospital	Preventative Care Engages in preventative care because the AI helps patients navigate health challenges through screening to help prevent patients from returning to the hospital
Ark. Dep't of Human Servs. v. Ledgerwood DAIL: Low income plaintiffs with physical disabilities sued the Department of Health Services, which replaced their nurse assessment questionnaire to an algorithm that drastically reduced attendant care, overriding physicians' decisions for necessary care	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
K.W. v. Armstrong DAIL: Class action settlement after the ACLU of Idaho sought injunctive relief against the Department of Health and Welfare for cutting disabilities services to "dangerously low levels" because of a trade secret algorithm	Clinical Decision Making Engages in clinical decision making because the AI limited their disability benefits, forcing patients to pursue treatment options by depriving them of needed services
Michael T. v. Bowling DAIL: West Virginia residents with intellectual and developmental disabilities brought a case against the West Virginia Department of Health and Human Resources for an AI system used to determine eligibility for	Clinical Decision Making Engages in clinical decision making because the AI limited their disability benefits, forcing patients to pursue treatment options by depriving them of needed services
C.S. et al v. Saiki DAIL: Oregon residents relying on in-home attendants were granted an injunction against an algorithm that vastly cut their hours, and ordered restoration of their previous algorithm that produced expected hours for disabilities	Clinical Decision Making Engages in clinical decision making because the AI limited their disability benefits, forcing patients to pursue treatment options by depriving them of needed services
Barrows et al v. Humana, Inc DAIL: Human used AI tools to improperly deny medical claims under Medicare Advantage plans while ignoring clinical determinations made by providers, preventing patients from affording critical treatments and harm patient health	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
Barrows et al v. Humana, Inc O'Neil Institute Tracker: Human used AI tools to improperly deny medical claims under Medicare Advantage plans while ignoring clinical determinations made by providers, preventing patients from affording critical treatments and harm patient health	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
Case/Harm	Task
Humania sued for using AI to unfairly deny health insurance to elderly patients AIAAIC: A class-action lawsuit accused US healthcare insurer Humana of illegally using the nH Predict AI model to override physicians' recommendations and prematurely terminate rehabilitation coverage for elderly patients.	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
nH Predict post-acute care algorithm accused of having a 90 percent error rate AIAAIC: A US lawsuit accuses the United-Health Group of deploying an AI-powered algorithm that unfairly denies post-acute care claims for Medicare Advantage patients 90 percent of the time, even against the advice of families and clinicians.	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
Estate of Gene B. Lokken et al. v. UnitedHealth Group, Inc. DAIL: Health insurer UnitedHealthcare is facing a class action alleging it used an artificial intelligence algorithm to override physician recommendations and wrongfully deny coverage to elderly people for care under their Medicare Advantage policies.	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
Estate of Gene B. Lokken et al. v. UnitedHealth Group, Inc. O'Neil Institute Tracker: Health insurer UnitedHealthcare is facing a class action alleging it used an artificial intelligence algorithm to override physician recommendations and wrongfully deny coverage to elderly people for care under their Medicare Advantage policies.	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
Investigation: nH Predict used to deny elderly peoples' Medicare Advantage benefits AIAAIC: nH Predict and similar tools are being used by insurance companies to determine whether patients enrolled in US Medicare Advantage programmes are worthy of care, and are driving the denial of benefits. It later emerged that NavHealth clinicians were becoming increasingly concerned that UnitedHealth bosses were letting nH Predict overrule their medical expertise.	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care that overrode physicians' clinical decision making
TennCare automated system accused of illegally denying Medicaid AIAAIC: A US District Court judge ruled that TennCare's automated Eligibility Determination System (TEDS) wrongfully terminated Medicaid coverage for thousands of Tennessee residents; the problems left many without access to necessary medical care, caused financial hardship, and emotional and psychological damage.	Clinical Decision Making Engages in clinical decision making because the AI limited their coverage based on what it determined as medically necessary care, depriving them of needed services
EviCore algorithm accused of helping health insurance companies deny care AIAAIC: Cigna subsidiary EviCore has been accused of using an AI-driven algorithm to systematically deny health insurance claims, potentially endangering patients' lives and well-being while boosting insurers' profits; failed to adhere to proper medical guidelines	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care, forcing patients to forgo important procedures or pay substantial out-of-pocket costs
Kisting-Leung et al. v. Cigna Corporation et al. DAIL: Class action lawsuit in California alleging that Cigna used an algorithm to wrongfully deny claims to patients seeking care recommended by medical providers	Clinical Decision Making Engages in clinical decision making because the AI provided recommendations around necessary care, forcing patients to forgo important procedures or pay substantial out-of-pocket costs

Figure 8: (continued) The legal cases and harms we tracked in our case study.
